Note: the distance metric,  $2N(Q_N - \tilde{Q}_N)$ , is the difference between the optimally weighted gmm criterion at the restricted estimates and its value at the relaxed estimates. It has a  $\chi^2$  distribution with degrees of freedom equal to the number of constraints that are relaxed. Standard errors are indicated in parentheses *except* for the distance metric, which reports a p-value.

This table presents results from 500 Monte Carlo samples of each estimator. Estimator 1 assumes inputs are perfectly measured and performs NLLS on production outcomes. Estimator 2 assumes measurement error in input 2 and uses relative demand observations to impute the second input, but does not impose cross-equation restrictions between demand and production when performing NLLS. Estimator 3 imposes the cross-equation restrictions. Estimator 4 implements estimator 1 assuming the true value of  $\rho$ .
